

NCERT IN TEXT QUESTIONS

10.1. Write structures of the following compounds:

- (i) 2-Chloro-3-methylpentane
- (ii) 1-Chloro-4-ethylcyclohexane
- (iii) 4-tert. Butyl-3-iodoheptane
- (iv) 1,4-Dibromobut-2-ene
- (v) 1-Bromo-4-sec. butyl-2-methylbenzene.

Ans:

10.2. Why is sulphuric acid not used during the reaction of alcohols with KI?

Ans. H_2SO_4 is an oxidising agent. It oxidises HI produced during the reaction to I_2 and thus prevents the reaction between an alcohol and HI to form alkyl iodide. To prevent this, a non-oxidising acid like H_3PO_3 is used.

10.3. Write structures of different dihalogen derivatives of propane.

Ans: Four isomers are possible. These are :

10.4. Among the isomeric alkanes of molecular formula C_5H_{12} ,

identify the one that on photochemical chlorination yields

(i) A single monochloride.

(ii) Three isomeric monochlorides.

(iii) Four isomeric monochlorides.

Ans:

H-atoms are equivalent, the replacement of any one of them gives the same product.

(ii) $\overset{a}{\text{CH}_3}\overset{b}{\text{CH}_2}\overset{c}{\text{CH}_2}\overset{b}{\text{CH}_2}\overset{a}{\text{CH}_3}$ *n*-pentane. *a*, *b*, *c* are the three sets of equivalent hydrogens. Therefore, three isomeric monochlorides are possible.

there are four sets of equivalent hydrogens Designated as *a*, *b*, *c*, *d*. Thus, four isomeric monochlorides are possible.

10.5. Draw the structures of major monohalo products in each of the following reactions:

Ans:

10.6. Arrange each set of compounds in order of increasing boiling points.

(i) Bromomethane, Bromoform, Chloromethane, Dibromomethane.

(ii) 1-Chloropropane, Isopropyl chloride, 1-Chlorobutane.

Ans:

(i) Chloromethane < Bromomethane < Dibromomethane < Bromoform

The reason is:

(a) for same alkyl group, B.Pt increases with size of halogen atom.

(b) B.Pt increases as number of halogen atoms increase.

(ii) Isopropyl chloride < 1 - Chloropropane < 1 - Chlorobutane

Reason:

(a) For same halogen, B.Pt. increases as size of alkyl group increases.

(b) B.Pt. decreases as branching increases.

10.7. Which alkyl halide from the following pairs would you expect to react more rapidly by an $\text{S}_{\text{N}}2$ mechanism? Explain your answer.

Ans: In $\text{S}_{\text{N}}2$ mechanism, reactivity depends upon the steric hindrance around the C-atom carrying the halogen. Lesser the steric hindrance, faster the reaction.

As steric hindrance in 2° alkyl halide is more, thus reactivity of $\text{CH}_3\text{CH}_2\text{CH}_2\text{CH}_2\text{Br} > \text{CH}_3\text{CH}_2\text{CH}(\text{Br})\text{CH}_3$

As steric hindrance in $(\text{CH}_3)_3\text{CBr}$ is more, thus it is less reactive than $\text{CH}_3\text{CH}_2\text{CH}(\text{Br})\text{CH}_3$

(iii) Both are 2° alkyl halides but CH_3 group at C_2 is closer to Br atom than $-\text{CH}_3$ group at C_3 . As a result $\text{CH}_3\text{CH}_2\text{CH}(\text{CH}_3)\text{CH}_2\text{Br}$ suffers greater steric hindrance than $\text{CH}_3\text{CH}(\text{CH}_3)\text{CH}_2\text{CH}_2\text{Br}$ and will thus be less reactive in $\text{S}_{\text{N}}2$.

10.8. In the following pairs of halogen compounds, which compound undergoes faster $\text{S}_{\text{N}}1$ reaction?

Ans:

Reactivity in $\text{S}_{\text{N}}1$ is governed by stability of carbocations.

10.9. Identify A, B, C, D, E, R and R¹ in the following:

Ans:

10.10. A hydrocarbon C₅H₁₀ does not react with chlorine in dark but gives a single monochloro compound C₅H₉Cl in bright sunlight. Identify the hydrocarbon.

Ans: The hydrocarbon with molecular formula C_5H_{10} can either be a cycloalkane or an alkene. Since the compound does not react with Cl_2 in the dark, therefore it cannot be an alkene but must be a cycloalkane. Since the cycloalkane reacts with Cl_2 in the presence of bright sunlight to give a single monochloro compound, C_5H_9Cl , therefore, all the ten hydrogen atoms of the cycloalkanes must be equivalent. Thus, the cycloalkane is cyclopentane.
