

Some Applications of Trigonometry Ex 12.1 Q49

Answer :

Let PQ be the tower of height H m and an angle of elevation of the top of tower PQ from point X is 60° . Angle of elevation at 40 m vertical from point X is 45° .

Let $PQ = H$ m and $SX = 40$ m. $OX = x$, $\angle PST = 45^\circ$, $\angle PXQ = 60^\circ$.

Here we have to find height of tower.

The corresponding figure is as follows

We use trigonometric ratios.

In $\triangle PST$

$$\Rightarrow \tan 45^\circ = \frac{h}{x}$$

$$\Rightarrow 1 = \frac{h}{x}$$

$$\Rightarrow x = h$$

Again in $\triangle PXQ$,

$$\Rightarrow \tan 60^\circ = \frac{h + 40}{x}$$

$$\Rightarrow \sqrt{3} = \frac{h + 40}{x}$$

$$\Rightarrow h + 40 = \sqrt{3}h$$

$$\Rightarrow h(\sqrt{3} - 1) = 40$$

$$\Rightarrow h = \frac{40}{\sqrt{3} - 1}$$

$$\Rightarrow h = 54.64$$

$$\text{Therefore } H = 54.64 + 40$$

$$\Rightarrow H = 94.64$$

Hence the height of tower is **94.64 m**.

Answer :

Let AB be the surface of lake and P be the point of observation such that $AP=2500$ m. Let C be the position of cloud and C' be the reflection in the lake. Then $CB=C'B$

Let PQ be the perpendicular from P on CB .

Let $PQ = x$ m, $CQ = h$, $QB = 2500$ m. then $CB = h + 2500$ consequently $C'B = h + 2500$ m. and $\angle CPQ = 15^\circ$, $\angle QPC' = 45^\circ$.

Here we have to find height of cloud.

We use trigonometric ratios.

In $\triangle PCQ$,

$$\Rightarrow \tan 15^\circ = \frac{CQ}{PQ}$$

$$\Rightarrow 2 - \sqrt{3} = \frac{h}{x}$$

$$\Rightarrow x = \frac{h}{2 - \sqrt{3}}$$

Again in $\triangle PQC'$,

$$\Rightarrow \tan 45^\circ = \frac{QB + BC'}{PQ}$$

$$\Rightarrow 1 = \frac{2500 + h + 2500}{x}$$

$$\Rightarrow x = 5000 + h$$

$$\Rightarrow \frac{h}{2 - \sqrt{3}} = 5000 + h$$

$$\Rightarrow h = 2500(\sqrt{3} - 1)$$

$$\Rightarrow CB = 2500 + 2500(\sqrt{3} - 1)$$

$$\Rightarrow CB = 2500\sqrt{3}$$

Hence the height of cloud is $\boxed{2500\sqrt{3}}$ m.

Answer :

Let C' be the image of cloud C . We have $\angle CAB = \alpha$ and $\angle BAC' = \beta$.

Again let $BC = x$ and AC be the distance of cloud from point of observation.

We have to prove that

$$AC = \frac{2h \sec \alpha}{(\tan \beta - \tan \alpha)}$$

The corresponding figure is as follows

We use trigonometric ratios.

In $\triangle ABC$

$$\Rightarrow \tan \alpha = \frac{BC}{AB}$$

$$\Rightarrow \tan \alpha = \frac{x}{AB}$$

Again in $\triangle ABC'$

$$\Rightarrow \tan \beta = \frac{BC'}{AB}$$

$$\Rightarrow \tan \beta = \frac{x + 2h}{AB}$$

Now,

$$\Rightarrow \tan \beta - \tan \alpha = \frac{x + 2h}{AB} - \frac{x}{AB}$$

$$\Rightarrow \tan \beta - \tan \alpha = \frac{2h}{AB}$$

$$\Rightarrow AB = \frac{2h}{\tan \beta - \tan \alpha}$$

Again in $\triangle ABC$

$$\Rightarrow \cos \alpha = \frac{AB}{AC}$$

$$\Rightarrow AC = \frac{AB}{\cos \alpha}$$

$$\Rightarrow AC = \frac{2h \sec \alpha}{(\tan \beta - \tan \alpha)}$$

Hence distance of cloud from points of observation is

$\frac{2h \sec \alpha}{\tan \beta - \tan \alpha}$

***** END *****
