

### Some Applications of Trigonometry Ex 12.1 Q61

**Answer :**

Let  $AB$  be the building of height 60 and  $CD$  be the lamp post of height  $h$ , an angle of depression of the top and bottom of vertical lamp post are  $30^\circ$  and  $60^\circ$  respectively. Let  $AE = h$ ,  $AC = x$  and  $AC = ED$ . It is also given  $AB = 60$  m. Then  $BE = 60 - h$  And  $\angle ACB = 60^\circ$ ,  $\angle BDE = 30^\circ$

We have to find the following

- The horizontal distance between  $AB$  and  $CD$
- The height of lamp post
- The difference between the heights of building and the lamp post

We have the corresponding figure as follows

(i) So we use trigonometric ratios.

In  $\triangle ABC$

$$\Rightarrow \tan 60^\circ = \frac{AB}{AC}$$

$$\Rightarrow \sqrt{3} = \frac{60}{x}$$

$$\Rightarrow x = \frac{60}{\sqrt{3}}$$

$$\Rightarrow x = 34.64$$

Hence the distance between  $AB$  and  $CD$  is **34.64**

(ii) Again in  $\triangle BDE$

$$\Rightarrow \tan 30^\circ = \frac{BE}{DE}$$

$$\Rightarrow \frac{1}{\sqrt{3}} = \frac{60-h}{x}$$

$$\Rightarrow \frac{60}{\sqrt{3}} = (60-h)\sqrt{3}$$

$$\Rightarrow 60 = 180 - 3h$$

$$\Rightarrow 60 = 180 - 3h$$

$$\Rightarrow 3h = 180 - 60$$

$$\Rightarrow 3h = 120$$

$$\Rightarrow h = 40$$

Hence the height of lamp post is **40** m.

(iii) Since  $BE = 60 - h$

$$\Rightarrow BE = 60 - 40$$

$$\Rightarrow BE = 20$$

Hence the difference between height of building and lamp post is **20** m.

### Some Applications of Trigonometry Ex 12.1 Q62

**Answer :**

Let  $h$  be the height of light house  $AC$ . And an angle of depression of the top of light house from two ships are  $\alpha$  and  $\beta$  respectively. Let  $BC = x$ ,  $CD = y$ . And  $\angle ABC = \alpha$ ,  $\angle ADC = \beta$ .

We have to find distance between the ships  
We have the corresponding figure as follows

We use trigonometric ratios.

In  $\triangle ABC$

$$\Rightarrow \tan \alpha = \frac{AC}{BC}$$

$$\Rightarrow \tan \alpha = \frac{h}{x}$$

$$\Rightarrow x = \frac{h}{\tan \alpha}$$

Again in  $\triangle ADC$

$$\Rightarrow \tan \beta = \frac{AC}{CD}$$

$$\Rightarrow \tan \beta = \frac{h}{y}$$

$$\Rightarrow y = \frac{h}{\tan \beta}$$

Now,

$$\Rightarrow BD = x + y$$

$$\Rightarrow BD = \frac{h}{\tan \alpha} + \frac{h}{\tan \beta}$$

$$\Rightarrow BD = \frac{h(\tan \alpha + \tan \beta)}{\tan \alpha \tan \beta}$$

Hence the distance between ships is  $\boxed{\frac{h(\tan \alpha + \tan \beta)}{\tan \alpha \tan \beta}}$ .

### Some Applications of Trigonometry Ex 12.1 Q63

**Answer :**

Let  $AB$  be the height of tower 50 m and angle of depression from the top of tower are  $60^\circ$  and  $30^\circ$  respectively at two observing Car C and D.

Let  $BD = x$  m,  $CD = y$  m and  $\angle ADB = 30^\circ$ ,  $\angle ACB = 60^\circ$

We have the corresponding figure as follows

So we use trigonometric ratios.

In a triangle  $ABD$ ,

$$\Rightarrow \tan D = \frac{AB}{BD}$$

$$\Rightarrow \tan 30^\circ = \frac{50}{x}$$

$$\Rightarrow \frac{1}{\sqrt{3}} = \frac{50}{x}$$

$$\Rightarrow x = 50\sqrt{3}$$

Since  $x = 86.6$

Again in a triangle  $ABC$

$$\Rightarrow \tan C = \frac{AB}{BC}$$

$$\Rightarrow \tan 60^\circ = \frac{50}{x-y}$$

$$\Rightarrow \sqrt{3} = \frac{50}{x-y}$$

$$\Rightarrow \sqrt{3} \times 50\sqrt{3} - \sqrt{3}y = 50$$

$$\Rightarrow y = 57.67$$

$$\text{Therefore } x - y = 86.6 - 57.67$$

$$\Rightarrow x - y = 28.93$$

Hence the distance of first car from tower is  $\boxed{86.6}$  m

And the distance of second car from tower is  $\boxed{57.67}$  m

And the distance between cars is  $\boxed{28.93}$  m.
