

## Mean Value Theorems Ex 15.2 Q8

Here

$$y = x^3 - 3x$$

y is a polynomial function, so it is continuous differentiable, so

Lagrange's mean value theorem is applicable thus there exists a point c such that,

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

$$\Rightarrow 3c^2 - 3 = \frac{f(2) - f(1)}{2 - 1}$$

$$\Rightarrow 3c^2 - 3 = \frac{2+2}{1}$$

$$\Rightarrow$$
  $3c^2 = 7$ 

$$\Rightarrow \qquad c = \pm \sqrt{\frac{7}{3}}$$

$$\Rightarrow y = \mp \frac{2}{3} \sqrt{\frac{7}{3}}$$

So, 
$$(c,y) = \left(\pm\sqrt{\frac{7}{3}}, \pm\frac{2}{3}\sqrt{\frac{7}{3}}\right)$$
 is the required point.

## Mean Value Theorems Ex 15.2 Q9

Here,

$$y = x^3 + 1$$

It is a polynomial function, so it is continuous differentiable.

 $\Rightarrow$  Lagrange's mean value theorem is applicable, so there exists a point c such that,

$$\Rightarrow \qquad \text{Lagrange's mean } v$$

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

$$\Rightarrow \qquad 3c^2 = \frac{f(3) - f(1)}{3 - 1}$$

$$\Rightarrow \qquad 3c^2 = \frac{28 - 2}{2}$$

$$\Rightarrow \qquad c^2 = \frac{13}{3}$$

$$\Rightarrow \qquad c = \sqrt{\frac{13}{3}}$$

$$\Rightarrow \qquad y = \left(\frac{13}{3}\right)^{\frac{3}{2}} + 1$$

So, 
$$(c,y) = \left(\sqrt{\frac{13}{3}}, \left(\frac{13}{3}\right)^{\frac{3}{2}} + 1\right)$$
 is the required point.

Mean Value Theorems Ex 15.2 Q10

Trigonometric functions are continuous and differentiable.

Thus, the curve C is continuous between the points (a,0) and (0,a) and is differentiable on [a,a]. Therefore, by Lagrange's Mean Value Theorem, there exists a real number  $c \in (a,a)$  such that

$$f(c) = \frac{a-0}{0-a} = -1$$

Now consider the parametric functions of the given function

$$x = a \cos^3 \theta$$

and

 $y = a \sin^3 \theta$ 

$$\Rightarrow \frac{dx}{d\theta} = 3a\cos^2\theta \left(-\sin\theta\right)$$

and

$$\Rightarrow \frac{dy}{d\theta} = 3a \sin^2 \theta (\cos \theta)$$

$$\Rightarrow \frac{dy}{dx} = \frac{\frac{dy}{d\theta}}{\frac{dx}{d\theta}}$$

$$\Rightarrow \frac{dy}{dx} = \frac{3a\sin^2\theta(\cos\theta)}{3a\cos^2\theta(-\sin\theta)}$$

$$\Rightarrow \frac{dy}{dx} = -\tan\theta$$

Slope of the chord joining the points (a,0) and (0,a)

=Slope of the tangent at (c, f(c)), where c lies on the curve

$$\Rightarrow \frac{a-0}{0-a} = -\tan\theta$$

$$\Rightarrow -1 = -\tan\theta$$

$$\Rightarrow$$
 tan  $\theta = 1$ 

$$\Rightarrow \theta = \frac{\pi}{4}$$

Now substituting  $\theta = \frac{\pi}{4}$ , in the

parametric representations, we have,

$$x = a\cos^3\theta, y = a\sin^3\theta$$

$$\Rightarrow x = a\cos^3\left(\frac{\pi}{4}\right), y = a\sin^3\left(\frac{\pi}{4}\right)$$

$$\Rightarrow x = \frac{a}{2\sqrt{2}}, y = \frac{a}{2\sqrt{2}}$$

Thus,  $P\left(\frac{a}{2\sqrt{2}}, \frac{a}{2\sqrt{2}}\right)$  is a point on C, where the tangent

is parallel to the chord joining the points (a,0) and (0,a).

Mean Value Theorems Ex 15.2 Q11

Consider the function as

$$f\left(x\right) = \tan x, \qquad \left\{x \in \left[a,b\right] \text{ such that } 0 < a < b < \frac{\pi}{2}\right\}$$

We know that  $\tan x$  is continuous and differentiable in  $\left(0,\frac{\pi}{2}\right)$ , so, Lagrange's mean value theorem is applicable on (a,b), so there exists a point c such that,

$$f'(c) = \frac{f(b) - f(a)}{b - a}$$

$$\Rightarrow \sec^2 c = \frac{\tan b - \tan a}{b - a} \qquad ---(i)$$

Now,

$$c \in (a, b)$$

$$\Rightarrow$$
 sec<sup>2</sup>a < sec<sup>2</sup>c < sec<sup>2</sup>b

$$\Rightarrow \sec^2 a < \sec^2 c < \sec^2 b$$

$$\Rightarrow \sec^2 a < \left(\frac{\tan b - \tan a}{b - a}\right) < \sec^2 b$$

Using equation (i),

$$\Rightarrow \qquad (b-a)\sec^2 a < (\tan b - \tan a) < (b-a)\sec^2 b$$
